

Module 3 – Cybersecurity and Cyber Defence

1. This demonstration simulates a complete cyber attack lifecycle against a military information system. The scenario begins with a phishing email delivered to a user workstation. Participants are required to identify indicators of phishing, suspicious links and malicious attachments.
2. Once the phishing email is opened, a simulated credential harvesting page is presented. Participants observe how weak passwords and poor authentication practices can lead to unauthorized access to sensitive systems. A practical Wireshark demonstration is conducted to analyse network traffic and illustrate how insecure authentication methods may expose sensitive information, emphasizing the importance of secure communication protocols, strong passwords and Multi-Factor Authentication (MFA).
3. Following credential compromise, participants conduct a vulnerability identification exercise on a workstation containing intentionally introduced security weaknesses, including weak passwords, outdated software, misconfigured accounts and insecure browser settings. The exercise demonstrates how attackers exploit vulnerabilities to gain further access.
4. The final stage consists of a cyber incident response drill. Participants identify indicators of compromise, isolate the affected system, report the incident through the appropriate chain of command and initiate containment and recovery procedures. The exercise reinforces the importance of timely reporting and coordinated response during cyber incidents.
5. Together, the demonstration illustrates the relationship between cyber hygiene, password security, vulnerability management and incident response in protecting military information systems against modern cyber threats.
